NOVEL PARENTERAL VACCINE FORMULATIONS AND USES THEREOF
B. W. Lee
Signature

dn a'

The present invention concerns the field of parenteral vaccine formulations and adjuvant compositions comprising certain salts as adjuvants. Such novel parenteral vaccine formulations are used for generating an immune response in a subject, including a vertebrate such as a human, following administration of the vaccine formulation. The invention further relates to the use of these salts as adjuvants in parenteral vaccine formulations and adjuvant compositions, and to vaccine adjuvants comprising such salts.

BACKGROUND OF THE INVENTION

Immunological adjuvants are substances that, when administered together with an antigen, have the capacity to augment the immune response to the antigen. When used as a component in a vaccine formulation, the adjuvant improves the immunogenicity of the vaccine in the sense that it will enhance the immune response of the vaccinated subject, thereby reducing the amount of the vaccine component, or reducing the number of administrations needed to induce the desired immune response.

The induced effector immune response may either be of a humoral nature, i.e. an antibody response, or of a cellular nature, i.e. a cytotoxic T-cell response, or the effector response may be a mixture of both. Both cellular and humoral immune responses require help from T helper lymphocytes. Adjuvants that cause inflammation or induce pro-inflammatory cytokines will induce a Type-1 T helper response (Th₁) involving production of IL-12, IL-2 and INF γ . These cytokines support induction of cytotoxic T-

It has surprisingly been found that certain salts are particularly suited as adjuvants in vaccine formulations for parenteral administration. Such salts are further

particularly suited as components of adjuvant compositions.

Thus, the present invention concerns parenteral vaccine formulations comprising at least one immunogenic substance, and as an adjuvant one or more salts selected from salts formed with a Group 2 element of the Periodic Table selected from Mg, Ca, Sr, Ba and Ra, or a Group 4 element of the Periodic Table selected from Ti, Zr, Hf, and Rf, and hydrates thereof, with the proviso that the salt is not calcium phosphate, is not magnesium hydroxide in combination with aluminium hydroxide or aluminium oxide and is not calcium hydroxide in gel combination with zinc hydroxide, lecithin and polyalphaolefine.

The present invention further concerns adjuvant compositions comprising one or more salts selected from salts formed with a Group 2 element of the Periodic Table selected from Mg, Ca, Sr, Ba and Ra, or a Group 4 element of the Periodic Table selected from Ti, Zr, Hf, and Rf, and hydrates thereof, with the proviso that the salt is not calcium phosphate, is not magnesium hydroxide in combination with aluminium hydroxide or aluminium oxide and is not calcium hydroxide in gel combination with zinc hydroxide, lecithin and polyalphaolefine.

The present invention also relates to adjuvants comprising such salts.

In further aspects, the present invention concerns the use of the adjuvants and adjuvant compositions as components of vaccine formulations for parenteral

35

aluminium hydroxide as adjuvant, or containing no adjuvant, and as immunogenic substance *Tetanus toxoid*.

DETAILED DESCRIPTION OF THE INVENTION

5

As mentioned above, the mechanisms of action of adjuvants are not completely understood. There are, however, some general theoretical principles by which an adjuvant may exert its effect, namely

10

(1) the adjuvant may create a depot of the antigen resulting in a prolonged slow release over time, thereby reducing the need for booster vaccinations,

15

(2) the adjuvant may enhance antigen uptake by antigen presenting cells (APCs) allowing the antigen to gain access to intracellular antigen processing pathways, and

20

(3) the adjuvant may be pro-inflammatory, i.e. attract and activate macrophages, monocytes, and other cells of the immune system, or stimulate cytokine production.

25

Furthermore, several other factors relating to adjuvanicity are believed to promote the immunogenicity of antigens. These include

30

- (1) rendering antigens particulate, e.g. aluminium salts,
- (2) polymers or polymerisation of antigens,
- (3) slow antigen release, e.g. emulsions or micro-encapsulation,
- (4) bacteria and bacterial products, e.g. CFA,
- (5) other chemical adjuvants, e.g. poly-I:C, dextran sulphate and inulin,
- (6) cytokines, and
- 35 (7) antigen targeting to APC.

09025635-100904

While a number of adjuvants (e.g. aluminium salts, PLG, ISCOMs, MF59, MPL, IFA (Freund's incomplete adjuvant), CFA (Freund's complete adjuvant), Quil A, and Qs-21) have
5 been used in experimental and veterinary medicine, aluminium salts (aluminium hydroxide and aluminium phosphate) are currently the only adjuvants used routinely in humans.

10 Aluminium based vaccines are most commonly manufactured by mixing pre-formed aluminium phosphate or hydroxide gels with the antigen, resulting in adsorption of the antigen to the gel. Aluminium salts are believed to exert their effect as adjuvants by several mechanisms. It is
15 believed that aluminium salts create a depot of antigen at the site of injection, and attract various cells of the immune system, thus creating a local inflammatory environment. Aluminium salts are most likely taken up by antigen presenting cells. Particles of a size of or less
20 than 10 μm are effectively taken up by antigen presenting cells. The particle size of aluminium gels is 0.5-10 μm , making this plausible (see ref. 6).

Although aluminium salts are relatively cheap and easy to
25 manufacture and, in addition, have an excellent track record of safety and adjuvanticity, there are certain problems connected with the use of aluminium compounds. These include local reactions such as erythema, contact hypersensitivity, subcutaneous nodules, and granulomatous
30 inflammation, augmentation of specific and total IgE antibody responses (an undesired antibody type in certain pathogenic conditions such as allergies) in both experimental animals and in humans. In addition, aluminium salts have been reported to be ineffective as
35 adjuvants with some antigens, cf. Gupta et al. (ref. 1).

09525635-000901

A disturbing observation has further been reported. It has been suggested in some studies that aluminium can cause experimental degenerative disorders of the central nervous system, cf. Rao et al. (ref. 2). Although there, as yet, is no clinical evidence linking the use of aluminium-containing vaccines to the development of human neuro-degenerative disorders such as Alzheimer's disease, a connection has been postulated and widely debated, cf. Savory et al. (ref. 3). This has generated some anxiety concerning the continuous use of aluminium-containing adjuvants in humans, and the search for alternative, aluminium free adjuvants has been called for.

Also the use of magnesium hydroxide in combination with aluminium hydroxide has been studied. While magnesium hydroxide alone has a low adsorbent activity, it may enhance the activity of aluminium hydroxide as an adjuvant, cf. Stas et al (ref. 8).

Beryllium being the lightest metal with an atomic weight of 4 and a molecular weight of 9 has been known to act as an antigen and further it has been shown to act as an adjuvant promoting the production of IFN- and enhancing the properties of IL-12 in a study on Leishmania-susceptible mice, which are immunized with soluble leishmanial antigen. The ability of beryllium to synergize with IL-12 may be an important factor in the development of adjuvants. Accordingly, beryllium has been suggested potential for development as a vaccine adjuvant, cf. Lee et al (ref. 7).

Thus, many adjuvant candidates have been suggested. Many of these promising new adjuvant candidates have, however, failed to pass the developmental stage, because they have been shown to lack one or several of the characteristics

desired for adjuvants, when tested in pre-clinical trials, cf. Newman (ref. 4). Many adjuvant candidates have displayed unacceptable levels of toxicity, thus limiting the applicability to very serious conditions, such as chronic viral infection, cancer or HIV therapy, where the use of adjuvants inducing higher levels of local or systemic side effects may be more acceptable. Some of the candidates have proven too costly to manufacture, or the manufacturing and purification process is too complicated to be feasible. Furthermore, a good adjuvant for human use should display physico-chemical stability for longer periods, preferably a year, and some adjuvant candidates have proven to have a limited shelf life.

PLG polymers were initially developed for use as biodegradable surgical sutures, and depot-formulation of various hormones. The characteristics of PLG (biodegradability, documented safety in humans, and relatively easy manufacturing) made it an obvious vaccine delivery candidate. The system is based on encapsulation of the antigen, and, if necessary, other components in 1-100 μm microspheres. When the particle is degraded, the antigen is released. The kinetics of the release can be adjusted by altering the composition of the polymers. Smaller microspheres ($\leq 10 \mu\text{m}$) will be taken up by antigen presenting cells, thus targeting the antigen to immunocompetent tissues. The main drawback of the PLG technology is the harsh physical and chemical conditions needed in the manufacturing process, which may render this technology useless with certain labile antigens. Although a good safety profile of PLG has been established, the adjuvanticity of PLG vaccines still awaits critical evaluation in clinical trials, cf. Newman (ref. 4).

Oil in water emulsions such as MF59 (a squalene in water emulsion) are more liquid than water in oil emulsions, and are therefore not intended to form a depot of antigen at the site of injection. Rather, it is believed that the oil in water emulsions exert their adjuvant effect when droplets are taken up by antigen presenting cells, cf. O'Hagan et al. (ref. 5). The emulsion is prepared and subsequently the antigen added, thus making the technology suitable for fragile or labile antigens, or purposes where the retention of the three dimensional structure of the antigen is required, cf. Newman (ref. 4). The potency of MF59 vaccines is reportedly up to 50-fold higher than vaccines delivered as aluminium salt formulations, in a number of animal models, cf. O'Hagan et al. (ref. 5). The MF59 adjuvant reportedly induces an antibody response, rather than a cellular immune response, and is thus better suited for use in vaccines aiming at augmenting or inducing antibody responses, cf. Newman (ref. 4).

Other adjuvant systems such as Quil A, Qs-21 and ISCOMs are based on natural products, namely saponins (sterol and triterpenoid glycosides, derived from the bark of the Quilaja saponiaria tree). Quil A is a crude preparation of more than 20 Quilaja saponins, and is currently used for veterinary vaccine technology. However, owing to the heterogeneity and toxicity of the product, Quil A is not suitable for use in human vaccines. This lead to further purification of the individual saponins in Quil A. Experimental vaccine and toxicology studies led to the identification of the Qs-21 as the saponin best suited for use in human vaccines, cf. Newman (ref. 4). Both Quil A and Qs-21 can elicit cellular immune responses as well as antigen responses in experimental animals. Qs-21 is

currently being tested in clinical trials. ISCOMs (immunostimulatory complexes) are spherical, hollow particles composed of cholesterol, saponin and phospholipid. Vaccine studies in animals have shown that lower doses of saponins are required to induce similar immune responses, when ISCOMs formulations are used. However, ISCOMs are relatively complicated to manufacture, and the advantage over Qs-21 is still debated, cf. Newman (ref. 4).

As evident from the above, there is a need for suitable adjuvants, in particular such suited for human use. There are several key features which an ideal adjuvant candidate should most preferably display, namely

(1) Safety. The adjuvant should preferably be sufficient non-toxic and biodegradable, and preferably induce minimal local and systemic reactions.

(2) Potency. The adjuvant should preferably be able to reduce the amount of antigen and/or number of applications needed in order to induce a long-lasting immune response (be it an antibody or cellular response).

(3) Stability. The adjuvant should preferably be stable for longer periods, preferably for more than a year, at 4°C or room temperature. Also, the manufacturing process should not have any detrimental effect on the antigen.

(4) Manufacturing and costs. The adjuvant should preferably be easy and cheap to manufacture in order not to increase the manufacturing costs of the vaccine tremendously.

The present invention provides adjuvants which fulfil some or all of the above criteria. It has surprisingly been found that certain salts are capable of acting as adjuvants in parenteral vaccine formulations.

5

Thus, in a first aspect, the present invention relates to parenteral vaccine formulations comprising at least one immunogenic substance, and as an adjuvant one or more salts selected from salts formed with a Group 2 element of the Periodic Table or a Group 4 element of the Periodic Table, and hydrates thereof, with the proviso that the salt is not calcium phosphate.

15 The advantages of the adjuvant salts are numerous. It has surprisingly been found that these salts act as adjuvants when included in parenteral vaccine formulations, implying that it will in many cases be possible to reduce the amount of immunogenic substance needed to induce an immune response. Moreover, the adjuvanicity of these salts can in some cases induce an immune response with an earlier onset and/or prolonged persistence, when compared to a conventionally used adjuvant. Accordingly, the number of booster vaccinations to obtain and maintain the desired level of immunity may be reduced. Moreover, studies indicate that the use of the salts described herein in vaccine formulations for parenteral use will in some cases increase the magnitude of the immune response, even to greater extents than seen with the conventionally used aluminium hydroxide.

A reason for this could be that the adjuvant salts exert their effect as adjuvants by creating a depot of the immunogenic substance, resulting in a slow and prolonged release of the immunogenic substance over time. On the

T06000-000001

other hand, the salts could also promote uptake of the immunogenic substance by antigen presenting cells. It should, however, be emphasised that this is a hypothesis, and should therefore have no limiting effect.

5

The salts can be characterised by a number of physical-chemical properties. These properties are believed to influence the salt's ability to act as an adjuvant to a greater or lesser extent. For instance, the solubility constant, the lattice energy, the nature of binding (covalent binding contra ionic binding), the pH, the oxidation stage, the particle size, and the ability to adsorb the immunogenic substance could all be involved. The compounds listed in the Examples have a low solubility and high lattice energy. Furthermore, the vaccine formulations of the Examples are slightly alkaline. Thus, some of the characteristics may be important in connecting with adjuvanicity. However, it is to be understood that the above are hypotheses and therefore should have no limiting effect on the scope of the invention.

15
20

The salts falling within the definition above are known chemical compounds, and some are currently being applied in veterinary or human medicine as laxatives, antacids or in cosmetic applications, cf. the examples in the table below. None of the salts have previously been used in parenteral vaccine formulations as sole adjuvants.

v approved for veterinary use

5

As used herein, the term "adjuvant" refers to an immunological adjuvant. By this is meant a compound that is able to enhance the immune system's response to an immunogenic substance. The term "immunogenic" refers to a substance or active ingredient which when administered to a subject, either alone or with an adjuvant, induces an immune response in the subject. The term "immune response" includes specific humoral, i.e. antibody, as well as cellular immune responses, the antibodies being serologic as well as secretory and pertaining to the subclasses IgM, IgD, IgG, IgA and IgE as well as all isotypes, allotypes, and subclasses thereof. The term is further intended to include other serum or tissue components. The cellular response includes Type-1 and Type-2 T-helper lymphocytes, cytotoxic T-cells as well as natural killer (NK) cells.

The concept of vaccination/immunisation is based on two fundamental characteristics of the immune system, namely specificity and memory. The first vaccination/-

TOP SECRET

immunisation will initiate a response specifically directed to the antigen with which the subject was challenged. Furthermore, a population of memory B and T lymphocytes will be induced. Upon re-exposure to the antigen or the pathogen it is derived from, the immune system will be primed to respond much faster and much more vigorously, thus endowing the vaccinated/immunised individual with immunological protection against the pathogen.

It lies within the scope of the present invention to use one or more immunogenic substances in the vaccine formulation. A case where the vaccine comprises more than one immunogenic substance is the so-called combination vaccines.

Examples of immunogenic substances are antigens, allergens, allergoids, peptides, proteins, haptens, carbohydrates, peptide nucleic acids (PNAs, a sort of synthetic genetic mimic), and viral or bacterial material as well as analogues or derivatives thereof. In the present context, the term "analogues or derivatives" is intended to include modified forms of the immunogenic substance. The modification can be made by chemical modification or synthetic modification, e.g. by PEGylation (PEG = polyethylene glycol), biotinylation, deamination, maleination, substitution of one or more amino acids, by cross-linking, by glycosylation, or by other recombinant or synthetic technology. The term is also intended to include natural-occurring mutations, isoforms and retroinverse analogues.

In particular such immunogenic substances may be natural, recombinant or modified proteins or fragments thereof, antigens, allergens, allergoids, peptides, haptens

Rickettsia spp., Clostridium spp. like *C. difficile*, *C. botulinum* and *C. tetani*, Lactobacillus spp., Listeria spp., and Mycoplasma spp. like *M. pneumoniae* *M. hominis*, Plasmodium falciparum, and Leishmania donovani,

5

moulds and fungi such as Cladospodium, Alternaria, Aspergillus, Basidiomycetes, Candida albicans, and Penicillium,

10 allergoids such as glutaraldehyde or PEG modified allergen complexes.

Examples of immunogenic substances used in combination vaccines are immunogenic substances involved with
 15 Diphtheria-Tetanus-Wooping cough-Polio, Measles-Parotitis-Rubella, and Hepatitis A and B.

Non-limiting examples of allergens to be used in the parenteral vaccine of the invention include inhalation
 20 allergens originating i.a. from trees, grasses, herbs, fungi, house dust mites, storage mites, cockroaches and animal hair, feathers, and dandruff. Important pollen allergens from trees, grasses and herbs are such originating from the taxonomic orders of *Fagales*, *Oleales*
 25 and *Pinales* including i.a. birch (*Betula*), alder (*Alnus*), hazel (*Corylus*), hornbeam (*Carpinus*) and olive (*Olea*), the order of *Poales* including i.a. grasses of the genera *Lolium*, *Phleum*, *Poa*, *Cynodon*, *Dactylis* and *Secale*, the orders of *Asterales* and *Urticales* including i.a. herbs of
 30 the genera *Ambrosia* and *Artemisia*. Important inhalation allergens from fungi are i.a. such originating from the genera *Alternaria* and *Cladospodium*. Other important inhalation allergens are those from house dust mites of the genus *Dermatophagoides*, storage mites from the genus
 35 *Lepidoglyphys destructor*, those from cockroaches and

05925635-060904

those from mammals such as cat, dog, horse, cow, and bird. Further, allergens to be used may be derived from venom allergens including such originating from stinging or biting insects such as those from the taxonomic order of Hymenoptera including bees, wasps, and ants.

It is to be understood that the term derived from includes the naturally-occurring substance as well as isoforms thereof. Furthermore, the substance may be prepared by means of recombinant or synthetic techniques. Specific allergen components are known to the person skilled in the art and include e.g. *Bet v 1* (*B. verrucosa*, birch), *Aln g 1* (*Alnus glutinosa*, alder), *Cor a 1* (*Corylus avelana*, hazel) and *Car b 1* (*Carpinus betulus*, hornbeam) of the *Fagales* order. Others are *Cry j 1* (*Pinales*), *Amb a 1* and 2, *Art v 1* (*Asterales*), *Par j 1* (*Urticales*), *Ole e 1* (*Oleales*), *Ave e 1*, *Cyn d 1*, *Dac g 1*, *Fes p 1*, *Hol l 1*, *Lol p 1* and 5, *Pas n 1*, *Phl p 1* and 5, *Poa p 1*, 2 and 5, *Sec c 1* and 5, and *Sor h 1* (various grass pollens), *Alt a 1* and *Cla h 1* (fungi), *Der f 1* and 2, *Der p 1* and 2 (house dust mites, *D. farinae* and *D. pteronyssinus*, respectively), *Lep d 1*, *Bla g 1* and 2, *Per a 1* (cockroaches, *Blatella germanica* and *Periplaneta americana*, respectively), *Fel d 1* (cat), *Can f 1* (dog), *Equ c 1*, 2 and 3 (horse), *Apis m 1* and 2 (honeybee), *Ves g 1*, 2 and 5, *Pol a 1*, 2 and 5 (all wasps) and *Sol i 1*, 2, 3 and 4 (fire ant).

As specified above, the salts to be used as adjuvants in the vaccine formulations for parenteral use is such formed with a Group 2 or Group 4 element of the Periodic Table, i.e. salts formed with Mg, Ca, Sr, Ba, Ra, Ti, Zr, Hf, or Rf. Here it is to be understood that the salts are composed of a cationic part and an anionic part. The Group 2 or Group 4 elements constitute the cationic part.

The salts to be used may be so-called double salts. Hydrates, e.g. mono-, di-, tri-, tetra- and penta-hydrates, of the salts also lies within the scope of the invention. Di- or trications (e.g. tricalcium) are also
5 part of the scope of the invention. Di- or trianions (e.g. disulphate) are also a part of the scope of the invention.

The salt may be an organic salt or an inorganic salt.
10

When the salt is an organic salt, examples of anion part are acetates, oxalates, citrates, and tartrates.

The salt to be used in the present invention is
15 preferably an inorganic salt.

In an embodiment, the parenteral vaccine formulation according to the invention is such, wherein the adjuvant is selected from salts formed with oxides, peroxides,
20 hydroxides, carbonates, phosphates, pyrophosphates, hydrogenphosphates, dihydrogenphosphates, sulphates, and silicates,
and hydrates thereof,
however having regard to the proviso above.

25 In another embodiment, the parenteral vaccine formulation is such, wherein the adjuvant is selected from salts formed between Mg, Ca, Ba, Ti, or Zr, and oxide, peroxide, hydroxide, and/or carbonate,
30 and hydrates thereof.

In a particular embodiment, the parenteral vaccine formulation of the invention is such, wherein the adjuvant is selected from salts formed between
35

5 titanium and oxide, peroxide, hydroxide, and/or
carbonate, and

titanium and oxide, peroxide, hydroxide, and/or carbonate, and

and hydrates thereof.

20 calcium hydrogenphosphate, calcium dihydrogenphosphate,
calcium sulphate dihydrate, magnesium carbonate,
magnesium oxide, magnesium dioxide, magnesium sulphate,
trimagnesium phosphate, magnesium silicate, dimagnesium
trisilicate, magnesium trisilicate, titanium disulphate,
25 zirconium dioxide, zirconium hydroxide, zirconium
sulphate, strontium peroxide, and strontium carbonate.

zirconium dioxide, zirconium hydroxide, zirconium sulphate, strontium peroxide, and strontium carbonate.

30 magnesium hydroxide, magnesium carbonate hydroxide
pentahydrate, and titanium dioxide.

35 high lattice energy.

09925635-080901

In some cases, the parenteral vaccine formulation according to the invention may further comprise an additional adjuvant. Such additional adjuvant is selected from conventionally used adjuvants. Examples of such additional adjuvants include saponins such as Quil A and Qs-21, oil in water emulsions such as MF59, MPL, PLG, PLGA, aluminium salts, calcium phosphate, water in oil emulsions such as IFA (Freund's incomplete adjuvant) and CFA (Freund's complete adjuvant), interleukins such as IL-1 β , IL-2, IL-7, IL-12, and INF γ , Adju-Phos[®], glucan, antigen formulation, Cholera Holotoxin, liposomes, DDE, DHEA, DMPC, DMPG, DOC/Alum Complex, ISCOMs[®], muramyl dipeptide, monophosphoryl lipid A, muramyl tripeptide, and phosphatidylethanolamine (see also "Vaccine Design. The Subunit and Adjuvant Approach", Chapter 7 (ref. 6)). In a preferred embodiment, the additional adjuvant is selected from saponins such as Quil A and Qs-21, MF59, MPL, PLG, PLGA, calcium phosphate, and aluminium salts.

Furthermore, the parenteral vaccine formulation of the invention may suitably comprise one or more pharmaceutically acceptable excipients and carriers. Examples of such are diluents, buffers, suspending agents, wetting agents, solubilising agents, pH-adjusting agents, dispersing agents, preserving agents, and/or colorants.

The vaccine formulation of the inventions is administered by a parenteral route. The parenteral route includes intravenous, intramuscular, intraarticular, subcutaneous, intradermal, epicutaneous/transdermal, and intraperitoneal administration.

The cation of the adjuvant salt is preferably present in the vaccine in an amount of from about 0.0004 to about

The amount of the additional adjuvant depends on the
5 adjuvant and the immunogenic substance in question, and
will be the subject to optimisation. However, the person
skilled in the art will readily know how to optimise the
amount of such additional adjuvant having regard to the
other constituents to be included in the formulation.

In one embodiment of the parenteral vaccine formulation, the adjuvant is magnesium hydroxide. In another embodiment of the parenteral vaccine formulation, the adjuvant is magnesium carbonate hydroxide pentahydrate.

30

Furthermore, it may be possible to manufacture vaccine formulations having combined characteristics such as earlier onset, prolonged persistence, increased potency, Th₁, Th₂ and/or cytotoxic response depending on the choice of adjuvants or combination of adjuvants. Thus, it

5

10

25

30

Although the salt may be an organic or an inorganic salt, cf. above, the adjuvant composition of the invention is preferably such, wherein the salt is selected from inorganic salts.

5

In a preferred embodiment, the adjuvant composition is such, wherein the salt is selected from salts formed with oxides, peroxides, hydroxides, carbonates, phosphates, pyrophosphates, hydrogenphosphates, dihydrogenphosphates, 10 sulphates, and/or silicates, and hydrates thereof, however having regard to the proviso above.

As mentioned above, double salts are also part of the 15 present invention. Salts having di- or tri-cations or -anions are also part of the invention.

In particular, the adjuvant composition is such, wherein the salt is selected from salts formed between Mg, Ca, 20 Ba, Ti, or Zr, and oxide, peroxide, hydroxide, and/or carbonate, and hydrates thereof, however, having regard to the proviso above.

The adjuvant composition may particularly be such, 25 wherein the salt is selected from salts formed between

magnesium and oxide, peroxide, hydroxide, and/or carbonate, calcium and oxide, peroxide, hydroxide, and/or carbonate, 30 barium and oxide, peroxide, hydroxide, and/or carbonate, titanium and oxide, peroxide, hydroxide, and/or carbonate, and zirconium and oxide, peroxide, hydroxide, and/or carbonate, 35 and hydrates thereof.

T050990-5635-030504

In a special embodiment, the adjuvant composition is such, wherein the salt is selected from magnesium hydroxide, magnesium carbonate hydroxide pentahydrate, titanium dioxide, calcium carbonate, barium hydroxide, barium peroxide, barium carbonate, barium sulphate, beryllium oxide, calcium sulphate, calcium silicate, dicalcium silicate, tricalcium silicate, calcium pyrophosphate, calcium peroxide, calcium hydroxide, tricalcium phosphate, calcium hydrogenphosphate, calcium dihydrogenphosphate, calcium sulphate dihydrate, magnesium carbonate, magnesium oxide, magnesium dioxide, magnesium sulphate, trimagnesium phosphate, magnesium silicate, dimagnesium trisilicate, magnesium trisilicate, titanium disulphate, zirconium dioxide, zirconium hydroxide, zirconium sulphate, strontium peroxide, and strontium carbonate.

Preferably, the adjuvant composition is such, wherein the salt is selected from magnesium hydroxide, magnesium carbonate hydroxide pentahydrate, and titanium dioxide.

In some cases, it may be advantageous to include an additional adjuvant in the adjuvant composition. Thus, in one embodiment, the adjuvant composition of the invention further comprises an additional adjuvant. The additional adjuvant may suitably be selected from those mentioned above. In a preferred embodiment, the additional adjuvant is selected from saponins such as Quil A and Qs-21, MF59, MPL, PLG, PLG A, calcium phosphate, and aluminium salts.

The adjuvant composition of the invention may further comprise pharmaceutically acceptable excipients and/or carriers.

Furthermore, the adjuvant composition may comprise diluents, buffers, suspending agents, solubilising agents, pH-adjusting agents, dispersing agents, and/or colorants.

5

In the adjuvant composition of the invention which may be available as a powder or a gel or suspension, the cation of the salt may suitably be present in an amount of from about 0.0004 to about 120 M, such as from about 0.004 to
10 about 12 M, preferably from about 0.008 to about 6 M.

In one embodiment of the adjuvant composition, the salt is magnesium hydroxide. In another embodiment of the adjuvant composition, the salt is magnesium carbonate
15 hydroxide pentahydrate. In a third embodiment of the adjuvant composition, the salt is titanium dioxide. In a fourth embodiment of the adjuvant composition, the salt is a combination of magnesium hydroxide and magnesium carbonate hydroxide pentahydrate, magnesium hydroxide and
20 titanium dioxide, or magnesium carbonate hydroxide pentahydrate and titanium dioxide. In a fifth embodiment, the salt is a combination of magnesium hydroxide, magnesium carbonate hydroxide pentahydrate and titanium dioxide. Such adjuvant composition may suitably comprise
25 an additional adjuvant. Such additional adjuvants are suitably selected from those indicated above. In a preferred embodiment, the additional adjuvant selected from saponins such as Quil A and Qs-21, MF59, MPL, PLG, PLG A, calcium phosphate and aluminium salts.

30

In another embodiment, the salt(s) is (are) selected so as to have a low solubility and/or high lattice energy.

In a third aspect, the present invention relates to
35 adjuvants comprising one or more salts selected from

05925675-000901

salts formed with a Group 2 element of the Periodic Table selected from Mg, Ca, Sr, Ba and Ra, or a Group 4 element of the Periodic Table selected from Ti, Zr, Hf, and Rf, and hydrates thereof,

- 5 with the proviso that the salt is not calcium phosphate, is not magnesium hydroxide in combination with aluminium hydroxide or aluminium oxide and is not calcium hydroxide in gel combination with zinc hydroxide, lecithin and polyalphaolefine.

10

The adjuvant of the invention may comprise organic and/or inorganic salts.

- 15 In a preferred embodiment of the adjuvant of the invention, the salt is selected from inorganic salts.

- The adjuvant of the invention may suitably be such, wherein the salt is selected from salts formed with oxides, peroxides, hydroxides, carbonates, phosphates, pyrophosphates, hydrogenphosphates, dihydrogenphosphates, sulphates, and silicates, and hydrates thereof, however having regard to the proviso above.

- 20 In particular the adjuvant may be such, wherein the salt is selected from salts formed between Mg, Ca, Ba, Ti, or Zr, and oxide, peroxide, hydroxide, and/or carbonate, and hydrates thereof.

- 25 Particularly interesting adjuvants are such, wherein the salt is selected from salts formed between

magnesium and oxide, peroxide, hydroxide, and/or carbonate,

- 30 calcium and oxide, peroxide, hydroxide, and/or carbonate,

09025635-000901

barium and oxide, peroxide, hydroxide, and/or carbonate,
titanium and oxide, peroxide, hydroxide, and/or
carbonate, and
zirconium and oxide, peroxide, hydroxide, and/or
5 carbonate,
and hydrates thereof.

In one embodiment of the adjuvant of the invention, the
salt is selected from magnesium hydroxide, magnesium
10 carbonate hydroxide pentahydrate, titanium dioxide,
calcium carbonate, barium hydroxide, barium peroxide,
barium carbonate, barium sulphate, beryllium oxide,
calcium sulphate, calcium silicate, dicalcium silicate,
tricalcium silicate, calcium pyrophosphate, calcium
15 peroxide, calcium hydroxide, tricalcium phosphate,
calcium hydrogenphosphate, calcium dihydrogenphosphate,
calcium sulphate dihydrate, magnesium carbonate,
magnesium oxide, magnesium dioxide, magnesium sulphate,
trimagnesium phosphate, magnesium silicate, dimagnesium
20 trisilicate, magnesium trisilicate, titanium disulphate,
zirconium dioxide, zirconium hydroxide, zirconium
sulphate, strontium peroxide, and strontium carbonate.

In a preferred embodiment, the adjuvant is such, wherein
25 the salt is selected from magnesium hydroxide, magnesium
carbonate hydroxide pentahydrate, and titanium dioxide,
or the salt is selected from a combination of magnesium
hydroxide and magnesium carbonate hydroxide pentahydrate,
magnesium hydroxide and titanium dioxide, magnesium
30 carbonate hydroxide pentahydrate and titanium dioxide, or
magnesium hydroxide, magnesium carbonate hydroxide
pentahydrate, and titanium dioxide.

In a fourth aspect, the present invention relates to the
35 use of a salt formed with a Group 2 element of the

1060005926601

Periodic Table selected from Mg, Ca, Sr, Ba and Ra, or a Group 4 element of the Periodic Table selected from Ti, Zr, Hf, and Rf,

and hydrates thereof,

- 5 as an adjuvant in a vaccine formulation for parenteral administration,

with the proviso that the salt is not calcium phosphate, is not magnesium hydroxide in combination with aluminium hydroxide or aluminium oxide and is not calcium hydroxide

- 10 in gel combination with zinc hydroxide, lecithin and polyalpaolefine,

and to the use of a salt formed with a Group 2 element of the Periodic Table selected from Mg, Ca, Sr, Ba and Ra, or a Group 4 element of the Periodic Table selected from

- 15 Ti, Zr, Hf, and Rf,

and hydrates thereof,

as a component of an adjuvant composition,

with the proviso that the salt is not calcium phosphate, is not magnesium hydroxide in combination with aluminium

- 20 hydroxide or aluminium oxide and is not calcium hydroxide in gel combination with zinc hydroxide, lecithin and polyalpaolefine.

It lies within the scope of the invention to use the salts separately or in combination. The use of double salts also lies within the scope of the present invention as does the use of di- and tri- cationic or anionic salts.

- 30 The salt may be an organic or an inorganic salt, but preferably a salt selected from inorganic salts is used.

In particular, the salt to be used is selected from salts formed with oxides, peroxides, hydroxides, carbonates,

09925635-000904

phosphates, pyrophosphates, hydrogenphosphates, dihydrogenphosphates, sulphates, and silicates, and hydrates thereof.

- 5 In one embodiment, the salt to be used is selected from salts formed between Mg, Ca, Ba, Ti, or Zr, and oxide, peroxide, hydroxide, and/or carbonate, and hydrates thereof.
- 10 In another embodiment, the salt to be used is selected from salts formed between

magnesium and oxide, peroxide, hydroxide, and/or carbonate,

- 15 calcium and oxide, peroxide, hydroxide, and/or carbonate, barium and oxide, peroxide, hydroxide, and/or carbonate, titanium and oxide, peroxide, hydroxide, and/or carbonate, and zirconium and oxide, peroxide, hydroxide, and/or carbonate,
- 20 carbonate, and hydrates thereof.

- In a special embodiment, the salt to be used is selected from magnesium hydroxide, magnesium carbonate hydroxide pentahydrate, titanium dioxide, calcium carbonate, barium hydroxide, barium peroxide, barium carbonate, barium sulphate, calcium sulphate, tricalcium silicate, calcium pyrophosphate, calcium peroxide, calcium hydroxide, tricalcium phosphate, calcium hydrogenphosphate, calcium dihydrogenphosphate, calcium sulphate dihydrate,
- 30 magnesium carbonate, magnesium sulphate, trimagnesium phosphate, magnesium silicate, magnesium trisilicate, titanium disulphate, zirconium sulphate, strontium peroxide, and strontium carbonate.

35

09925635-080904

In a currently preferred embodiment, the salt to be used is selected from magnesium hydroxide, magnesium carbonate hydroxide pentahydrate, and titanium dioxide, or a combination of magnesium hydroxide and magnesium carbonate hydroxide pentahydrate, magnesium hydroxide and titanium dioxide, magnesium carbonate hydroxide pentahydrate and titanium dioxide, or magnesium hydroxide, magnesium carbonate hydroxide pentahydrate, and titanium dioxide.

In a fifth aspect, the present invention relates to methods of generating an immune response in a subject, which methods comprise administering to the subject a parenteral vaccine formulation of the invention.

In a sixth aspect, the present invention enables the vaccination or treatment of a vertebrate including a human being comprising administering to the subject a vaccine formulation of the invention.

As described above, the parenteral vaccine compositions of the present invention comprise at least one immunogenic substance. Thus, the inclusion of two, three, four, five, six or more immunogenic substances are contemplated and believed to be advantageous in some cases. The amount of immunogenic substance(s) depends on the immunogenic substance or combination of immunogenic substances in question. However, it is contemplated that the amount of immunogenic substance required to induce an immune response can, in some cases, be reduced due to the beneficial effects of the adjuvant salts. Thus, the amount of each immunogenic substance will typically be in the range of from 0.0001 to 100000 $\mu\text{g}/\text{dose}$, such as from 0.01 to 10000 $\mu\text{g}/\text{dose}$, from 0.1 to 1000 $\mu\text{g}/\text{dose}$, or from 1 to 100 $\mu\text{g}/\text{dose}$.

The administration of the vaccine formulation of the invention may be as single doses or as several doses. In certain cases, administration only once may be sufficient. In general, several doses should be given with intervals of a day, a week, two weeks, a month, or several months, etc. For example, a single dose may be given once, or a dose may be given as a primer, followed by one or more booster vaccinations, or a continuous vaccination regime like up to four doses per week, followed by one month without vaccinations, followed by up to four doses per week (optionally with increasing amount of immunogen), etc. Optionally different adjuvants or combination of adjuvants may be used in the different vaccinations. These are all examples, and the optimal vaccination regime depends on the immunogenic substance in question and several other factors. The person skilled in the art will readily know how to optimise this.

The adjuvant compositions of the invention can be prepared by forming a suspension or gel of the adjuvant salts by adding liquid, optionally containing buffer, other salts, solvents or excipients, to a dry form of the salt, or, alternatively, adding liquid optionally containing buffer, other salts, excipients, to a pre-equilibrated pre-formed gel of the adjuvant salts. The adjuvant composition may then be formulated to a vaccine formulation with desired immunogenic substance(s) by mixing the adjuvant composition with the immunogenic substance(s), and, if necessary, leaving them to equilibrate before filling. The adjuvant composition and the immunogenic substance(s) may alternatively be mixed in a more concentrated form, thereby enabling later dilution.

EXAMPLES

5 Immunogenic substance:
 Tetanus toxoid (TT) containing 3.0 mg protein/ml,
 (obtained from Statens Serum Institut, DK-2300 Copenhagen
 S, Denmark). Vaccine formulations containing aluminium
 hydroxide, as an adjuvant, contained either 30 µg, 10 µg
 10 or 1 µg TT per dose (300 µg/ml, 100 µg/ml, and 10 µg/ml,
 respectively), and vaccine formulations of the invention
 containing magnesium hydroxide, magnesium carbonate
 hydroxide pentahydrate or titanium dioxide, as an
 adjuvant of the invention, and the adjuvant free vaccine
 15 formulation (termed "no adjuvant") all contained 1 µg TT
 per dose (10 µg/ml).

20 The molar concentration stated below are for the final vaccine formulations:

25 Magnesium hydroxide, $\text{Mg}(\text{OH})_2$ 0.05 M Mg^{2+} . Prepared from $\text{Mg}(\text{OH})_2$ gel (Reheis, USA).

Titanium dioxide, TiO_2 , 0.05 M Ti^{4+} . Prepared from Titanium dioxide pigment (Kemira, Finland).

Preparation of the vaccine formulations:

The vaccine formulations were prepared as follows:

5 TT was dissolved or diluted to a concentration 10 times
that of the concentration in the final vaccine
formulation. The adjuvant was dissolved or diluted to a
concentration five times that of the concentration in the
final vaccine formulation, with regard to the cation. 1
10 volume TT solution was slowly mixed with 2 volumes
adjuvant, and left stirring over night at 4°C. The
following day 7 volumes Coca 0.0 buffer (0.25% sodium
hydrogen carbonate and 0.5% sodium chloride) was slowly
added. The adjuvant free vaccine was prepared as above,
15 with the modification that the adjuvant was substituted
with Coca 0.0 buffer.

Immunisations:

For each vaccine formulation, groups of 8 female BALB/Ca
mice, 6-8 weeks of age, were given subcutaneous
20 immunisations, inguinally, on days 0 and 14. Each
immunisation consisted of 100 µl vaccine.

Blood samples were drawn from the retro orbital vein
every 7 days, starting on day 0. Serum was separated from
25 the blood sample, and stored at -20°C, until analysed.

Analysing serum samples:

Serum samples were analysed for the presence of TT-
specific immune response by means of a direct enzyme
30 linked immunosorbent assay (ELISA), measuring TT-specific
antibodies of the IgG class. Briefly, immunosorbent
plates (Nunc Maxisorp®, Nunc, Denmark) were coated in a
well known manner with TT, and free binding sites were
blocked with bovine serum albumin. Serial dilutions of
35 serum samples from the immunised mice were then added

F05080"9E952550

onto the plate, together with serial dilutions of a negative control serum pool from unimmunised BALB/Ca mice. A monoclonal TT-specific antibody (obtained from Statens Serum Institut, Copenhagen, Denmark), added in
5 serial dilutions served both as a positive control, as well as an internal standard, used for determining the titre. All samples were added in duplicate.

Bound antibodies were detected by serial incubations of
10 the plate with a biotinylated, polyclonal antiserum to mouse IgG (obtained from Jackson Laboratories, Bar Harbour, ME, USA) followed by a streptavidine-horseradish peroxidase conjugate (obtained from DAKO A/S, Glostrup, Denmark). The plates were developed for 20 minutes with
15 100 µl readymade TMB substrate (Kem-En-Tech, Denmark) per well, and the reaction as stopped with an equal volume of 1M H₂SO₄.

The developed colour reaction was measured as absorption
20 at 450 nm.

Data analysis:

The absorption at 450 nm was plotted against the dilution of the serum, for each individual mouse, as well as the
25 geometric mean for individual groups.

The strength of the TT-specific antibody response in each serum sample was measured as an arbitrary titre, determined as the serum dilution giving an absorption
30 signal equal to 50% of that obtained with a 3000 fold dilution of the TT-specific monoclonal antibody. Mice that did not respond, i.e., whose responses were indistinguishable from those seen with the serum pool from unimmunised control mice, were assigned a titre of
35 10. Mice that responded, but with responses below the

09025635 "080901

magnitude required to determine a titre, were assigned a titre of 100.

EXAMPLE 1

5

One immunisation with vaccine formulations of the invention comprising either magnesium hydroxide, magnesium carbonate pentahydrate, or titanium dioxide as an adjuvant

10

The vaccines were prepared as described above, and the mice were immunised once on day 0 as described above. Blood was drawn on day 7, and serum was prepared and analysed as described above.

15

In Figure 1, the results are depicted as titres for individual mice, as well as the mean titre for each group. The adjuvant given is indicated below each group. The number in parenthesis indicates the amount (in μg) of immunogen (TT) given.

20

As can be seen from Figure 1, vaccine formulations comprising either magnesium hydroxide, magnesium carbonate pentahydrate, or titanium dioxide as an adjuvant, were more potent at inducing TT-specific antibodies, than vaccine formulation containing $\text{Al}(\text{OH})_3$ as an adjuvant. Induction of TT-specific antibodies using an $\text{Al}(\text{OH})_3$ -containing vaccine formulations required 10-30 times as much immunogen (TT) as vaccine formulations comprising either magnesium hydroxide, magnesium carbonate pentahydrate, or titanium dioxide as an adjuvant. Thus, the experiment clearly shows that when the adjuvants of the invention is included in parenteral vaccine formulations, the amount of antigen necessary to

25

30

00925635-080904

induce an immune response, following one immunisation, is reduced.

EXAMPLE 2

5

Immunisations with vaccine formulations of the invention comprising either magnesium hydroxide, magnesium carbonate pentahydrate, or titanium dioxide as an adjuvant

10

The vaccine formulations were prepared as described above, and the mice were immunised on day 0 and 14 with 1 µg of TT as described above. Blood was drawn every 7 days from day 0 to 42, and serum was prepared and analysed as described above.

15

Results, given as the geometric mean titre of the whole group, are shown for days 7 and 28 in Figure 2A and 2B. The adjuvant used is indicated below each group. As can be seen in Figure 2A, vaccine formulations comprising either magnesium hydroxide, magnesium carbonate pentahydrate, or titanium dioxide as an adjuvant induce specific immune responses with an earlier onset than vaccine formulations containing $\text{Al}(\text{OH})_3$ as an adjuvant. Furthermore, as can be seen in Figure 2B, following a second vaccination of all mice on day 14, the immune responses induced with vaccine formulations containing either magnesium hydroxide, magnesium carbonate pentahydrate, or titanium dioxide as an adjuvant, induce specific immune responses similar in magnitude to those induced by a vaccine containing $\text{Al}(\text{OH})_3$ as an adjuvant.

20

25

30

Thus, when the adjuvant salts are included in parenteral vaccine formulations, a persistent, specific immune response is induced. Furthermore, and earlier onset is

35

FOUO "SECRET"

observed, and the magnitude of the immune response is comparable to that seen with vaccine formulations containing $\text{Al}(\text{OH})_3$ as an adjuvant.
